MFGR: AIRESSEARCH

The present Item 8.17 Steam Duct Pressure Transducer (P/N 837036-1) has been determined to be unacceptable because of its inability to maintain a stable calibration. A majority of the calibration shift problems have occurred during acceptance testing, but some units have been rejected after use in the field and during qual testing. The reasons for the shifts have been:

- . Mechanical instability of the sensing diaphragm.
- . Sensitivity to minor overpressurization of the sensing diaphragm.
- . Corrosion of the diaphragm and the "E" core pole pieces caused by the moisture of the pressure media.
- . Gain shifts caused by internal electronic instability.
- . Calibration changes caused by pressure inlet fitting torque.

Because of the basic design problems associated with this unit it was deemed impractical to attempt to modify this design to obtain an acceptable transducer.

AiResearch has undertaken an extensive survey of other transducer manufacturers in an attempt to find an acceptable replacement. Test samples were obtained from six manufacturers that were judged to have a workable approach to this problem. A developmental test program was initiated and tests were conducted on the new transducers. Preliminary results of this testing have been transmitted to North American Rockwell by AiResearch Report No. DTD-183, dated 16 October 1967. Since that report, developmental testing has continued, and the development test results on one transducer type are very encouraging. The transducer is manufactured by the Pace-Wiancko Division of the Whittaker Corporation, North Hollywood, Calif. The results of this testing have indicated that the Pace-Wiancko transducer will meet or exceed the requirements for this application. As a result of the encouraging test results on the Pace-Wiancko transducer, a EDCP will be submitted to incorporate this transducer into the ECS system. Testing, however, will continue on both the Pace-Wiancko and transducers from other suppliers.

Foreign Nation Release

This information is furnished upon the condition that it will not be released to another Nation without specific authority of the cognizant agency (Military or NASA) of the United States Government, and that the information be provided substantially the same degree of protection afforded it by the Department of Defense of the United States.

Disclaimer of Liability from Act of Transmittal

When Government drawings, specifications, or other data are used for any purpose other than in connection with a definitely related Government procurement operation, the United States Government thereby incurs no responsibility nor any obligation whatsoever; and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specification, or other data, is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

Any information disseminated by the Data Distribution Centers of the Interservices Data Exchange Program is intended to promote test data utilization in the National interest among groups engaged in Ballistic Missile, Space Vehicle and related programs.

Dissemination of said information does not imply verification or endorsement of the information. The originator, in submitting the material is acting in accordance with the requirements of his contract, and neither the originator nor the disseminator assumes any liability to parties adopting any product, process or practice based upon the usage of the information. Its presenting the success or failure of one (or several) part number(s), model(s), lot(s) under specific environment and output requirements, does not imply that other products not herein reported on are either inferior or superior.

Omission of Charges for Follow-on Actions

Any compliance by the report originator with requests from recipients for more detailed information on IDEP reports originated under Government contracts will be considered within the scope of present contractual obligations. Compliance with such requests will be at the discretion of the report originator and will be performed without cost or obligation to the requestor unless otherwise negotiated in advance.

Reproduction of this Report

Reproduction or duplication of any portion of this report is expressly forbidden, except by those contractors receiving it directly from the Data Centers or originator, for their internal use or the use of their subcontractors. Reproduction or display of all or any portion of this material for any sales, advertising or publicity purposes is prohibited.

DEVELOPMENTAL DATA TRANSMITTAL
STEAM DUCT PRESSURE TRANSDUCER
ECS ITEM 8.17
NAR/SD PROJECT APOLLO
NAR P.O. M5J7XAZ-450029A

INTRODUCTION

The present Item 8.17 Steam Duct Pressure Transducer (P/N 837036-1) has been determined to be unacceptable because of its inability to maintain a stable calibration. A majority of the calibration shift problems have occurred during acceptance testing, but some units have been rejected after use in the field and during qual testing. The reasons for the shifts have been:

- Mechanical instability of the sensing diaphragm.
- Sensitivity to minor overpressurization of the sensing diaphragm.
- Corrosion of the diaphragm and the "E" core pole pieces caused by the moisture of the pressure media.
- Gain shifts caused by internal electronic instability.
- Calibration changes caused by pressure inlet fitting torque.

Because of the basic design problems associated with this unit it was deemed impractical to attempt to modify this design to obtain an acceptable transducer.

AIResearch has undertaken an extensive survey of other transducer manufacturers in an attempt to find an acceptable replacement. Test samples were obtained from six manufacturers that were judged to have a workable approach to this problem. A developmental test program was initiated and tests were conducted on the new transducers. Preliminary results of this testing have been transmitted to North American Rockwell by AIResearch Report No. DTD-183, dated 16 October 1967. Since that report, developmental testing has continued, and the development test results on one transducer type are very encouraging. The transducer is manufactured by the Pace-Wlancko Division of the Whittaker Corporation, North Hollywood, California. The results of this testing have indicated that the Pace-Wlancko transducer will meet or exceed the requirements for this application. As a result of the encouraging test results on the Pace-Wlancko transducer, a EDCP will be submitted to incorporate this transducer into the ECS system. Testing, however, will continue on both the Pace-Wlancko and transducers from other suppliers.

This report presents a summary of the development tests completed to date, on the Pace-Wlancko transducers. The testing was conducted from August 1967 through January 1968.

SUMMARY

Based on the successful completion of the developmental testing at this time a design decision has been made to submit an EDCP to incorporate the improved Pace-Wiancko into the steam duct pressure transducer application. This transducer is identified by Part Number 836706-2.

The decision is based on the results of the development tests and design investigations completed to this date on five test specimens. The Pace-Wiancko design incorporates a stretched diaphragm that has proved to be exceptionally stable during pressure cycling tests. No major problems were encountered either with moisture or electronic instability. The transducer is insensitive to fitting torque since the pressure fitting is installed with a torque of 150 lb-in. and securely locked with a set screw.

To further increase the confidence level in this design, development tests are continuing. Further tests will include water testing, corrosive contaminant oxygen-humidity testing (CCOH), continued steam environment testing and disassembly.

TEST SPECIMENS

Five development test transducers were obtained from Pace-Wiancko for this testing. The units are identified by the following serial and part numbers:

<u>Serial No.</u>	<u>Part Number</u>
22319	837036-2
22320	837036-2
22321	837036-2
22322	837036-2
22323	836706-2*

Initial delivery was taken on Part No. 837036-2 Serial Nos. 22319 through 22322, and testing was started. Tests on those units indicated that some design changes were desirable in order to improve the transducer stability. The design changes as discussed later in this report were:

1. Modification of the "E" core magnetic circuit to reduce magnetic circuit leakage.
2. Increased the diaphragm movement from approximately 0.0005 to 0.001 inch.
3. Improved pressure fitting installation procedure.
4. EMI filtering to meet SS-1313-R, Rev. I requirements.
5. Modification of sensing chamber to provide more space for possible contamination.
6. Improved case sealing: silicone adhesive instead of a gasket.

* Purchased as an 837036-2, but updated to an 836706-2 configuration with exception of improved electronic package sealing.

6. Improved case sealing: silicone adhesive instead of a gasket.

These changes have been incorporated into transducer S/N 22323, except for the improved case seal. The improved transducer design has been reidentified by Part Number 836706-2. Two transducers (S/N 22321 and 22322) are presently being reworked to incorporate the change. In other words, all of the tests included in this report were done on the initial configuration except for the tests conducted on unit S/N 22323, which had been revised to the new configuration.

The transducer has a double "E" core/diaphragm type pressure sensing element. The "E" cores are hermetically sealed under inconel covers. The case halves are made from passivated 416 type stainless steel, and the sensing diaphragm is made from 410 type stainless steel. To obtain a high degree of dimensional stability, the diaphragm is prestretched. This operation allows the diaphragm to be subjected to a considerable overpressure without calibration shift.

TEST DESCRIPTIONS

Five transducers were evaluated during this program. For clarity of presentation, the development tests and activities will be discussed separately for each transducer and not in the sequence in which the tests were done. Table 1 presents a summary of the tests completed to date on each test specimen. As shown on Table 1, a major portion of the test program has been completed on this unit. At the present time, the test program is continuing and the S/N 22323 is currently undergoing a water test. Future tests scheduled include further steam endurance testing where the transducer is operated while mounted on a steam generator, a corrosive contaminant oxygen-humidity test, and final disassembly inspection of the transducers.

Transducer 837036-2, S/N 22319 Testing

The S/N 22319 transducer was received from Pace-Wiancko and subjected to an initial calibration test. The results of this test and the results of the calibration test conducted by Pace-Wiancko are presented on Figure 1. The calibrations were quite similar and well within the ± 200 mv acceptable limit.

1. Pressure Cycling

Following the initial calibration test the transducer was subjected to 20,000 working pressure cycles between 0.05 and 0.30 psia. Calibration checks were conducted at intervals during this test. The results of these intermediate calibration checks are presented on Figure 2. Although the transducer appears to be out of calibration at the 4,750 cycle calibration, test equipment error is suspected to have caused these high readings. A post calibration test showed that the transducer was within the allowable tolerances. The results of this test are presented on Figure 3.

A pressure test was conducted by subjecting the transducer to 500 pressure cycles between approximately 0 and 14.7 psia. Following this test the transducer remained within calibration limits as shown by Curve 1 of Figure 4.

2. Extreme Temperature Test

Following the pressure testing the transducer was tested for calibration at the extreme temperatures of 0, 150 and 200°F. Room temperature calibration checks were made after the 0 and 200°F extremes. The results of this testing are presented on Figure 4.

3. Water Test

The transducer was then subjected to a water test. The sensing cavity of the transducer was filled with tap water, drained and allowed to stand at room temperature for a five day period. Tap water was used for this test in order to simulate to some degree the contaminates that may be present in waste water. However, as found by later analysis, the contamination level of tap water is excessive.

Following the five day storage period, the transducer was subjected to a calibration test. The results of that test are presented on Figure 5. The transducer was found to exceed the 4 percent maximum allowable calibration shift below approximately .175 psia.

As a result of this out of tolerance operation, the transducer was disassembled and examined. The sensing chamber was found to contain brown deposits on the diaphragm as shown on Figure 6.

Chemical analysis showed that the contamination did not originate within the transducer. The contamination was apparently deposits caused by the tap water. It was concluded that the calibration shift was caused by the deposition of contaminates between the pole pieces and the diaphragm while stored at room pressure. As the pressure was decreased the deposition tended to inhibit movement of the diaphragm to the low pressure position. This resulted in a positive shift of the transducer calibration.

It should be pointed out that this test is felt to be too severe because of the excessive contamination contained in tap water. This test is presently being repeated with distilled water which provides more realistic conditions.

Transducer 837036-2, S/N 22320 Testing

Following receipt of this transducer a calibration test was conducted to insure that the unit was within acceptable limits. The results of this test are presented on Figure 7.

The transducer was subjected to an ATP test per ATP SS-1759-R, ICM F. The data sheets from this test (Figure 8) show that the unit met the requirements and was acceptable.

1. Evaporator Steam Duct Test

The transducer was installed in the steam duct of an evaporator being used in a subsystem test. The transducer successfully sensed low-pressure steam pressure for a period of 282 hours. Intermediate calibration tests showed that the unit was functioning successfully (see Figure 9). Following the 282 hour exposure, the transducer was removed and subjected to a ATP test. The data sheets are presented on Figure 10.

2. Temperature Test per SS-1625-R

The transducer was installed into a test setup and subjected to the temperature profile as shown on Figure 11. No damage or degradation was observed as a result of this test. The post-test calibration data sheet is shown on Figure 12.

3. Vibration Test per SS-1560-R

The transducer was installed into a vibration fixture and supplied pressure of approximately 8 mm Hg A. Photographs of the setup in each axis are shown on Figure 13. The transducer was subjected to random vibration inputs simulating launch, flight and high G abort conditions. The inputs are presented on Figure 14. Data traces during vibration in the three axes are presented on Figure 15. The results of a post calibration test, conducted following vibration, are presented on Figure 16. The calibration showed that the transducer was within nominal requirements.

4. Shock Test per SS-1560-R

The transducer was subjected to a 78G shock test through the X+ axis. A photograph of the test setup is shown on Figure 17. The test was conducted at the Ogden Technology Laboratories, Inc., and their report is presented on Figure 18. A photograph of the shock calibration and impact shock trace is presented on Figure 19. A post test calibration check is presented on Figure 20. The transducer was within the required calibration limits.

5. Steam Endurance Test

A low pressure steam fixture was constructed to simulate the ECU evaporator steam environment in the pressure range between 5 and 10 mm Hg A. The fixture was capable of mounting up to eight transducers at one time, and could therefore expedite specimen exposures. The transducer was mounted on the fixture and was exposed to steam on a 24 hour a day basis. Performance was monitored on a continuous strip recording and was continuously within the nominal requirements. The transducers remained on the steam fixture in excess of 15 days, and a total of 360 hours were accumulated. Combining these hours with those accumulated on the previous evaporator steam test a total of 642 hours of life test cycles have been accumulated on this transducer.

6. Magnetic Field Effects

To determine the effect of a magnetic environment on the transducer operation, the transducer was mounted into a test setup and subjected to a magnetic field of 5 gauss. A calibration test was run at 0, 25, 50, 75, and 100 percent full scale, and at each level the magnetic field was changed from 0 to 5 to 0 gauss. A photograph of the test setup is shown on Figure 21. A data trace of this test is presented on Figure 22. The magnetic field resulted in no perceptible change in calibration at any level.

7. Attitude Test

An attitude test was performed to determine if the transducer is sensitive to any mounting attitude. The unit was pressurized to specific pressure levels within the calibration range. At each pressure level the transducer was calibration tested in both a + and - direction in the X, Y and Z axis. The results of this test are presented on Figure 23. No detrimental effects were observed and the unit was within calibration limits in all attitudes.

This transducer is presently awaiting further tests.

Transducer 837036-2, S/N 22321 Testing

After receipt of this transducer an ATP test was conducted per SS-1759-R, ICN F. The results of this test are presented on Figure 24. The transducer was out of calibration at the lower pressures. The transducer was returned to the supplier and a transformer was replaced, however, the calibration was still out of tolerance. A decision was made to retain this unit at AiResearch for development of the EMI filters since testing with S/N 22322 had revealed that the transducer did not meet the RF conducted susceptibility requirements. Discussion of that test is presented later in this report. Later failure analysis was to show that the shift was caused by a magnetic leakage problem.

1. EMI Test per SS-1313-R, Rev. I

The transducers was modified with three separate EMI filter systems based on the findings from the EMI tests on transducer S/N 22322. The final fix was successful, and the test report from Genisco Technology Corporation is included in Appendix A of this report.

2. Modification

Following the successful completion of the EMI test the unit was returned to the supplier for failure investigation and modification. The failure report is presented on Figure 25. The failure report shows that a basic design modification was necessary to improve the transducer magnetic circuit design. The transducer is presently at the supplier being modified to the improved design and with other changes necessary to bring the transducer to the P/N 836706-2 configuration.

AIRESEARCH MANUFACTURING DIVISION
Los Angeles, California

DTD-191
Page 6

10

Transducer 837036-2, S/N 22322

Following receipt of this transducer from the supplier, a calibration check showed the transducer was acceptable. The calibration data is presented on Figure 26.

1. Evaporator Steam Duct Test

Following the initial calibration test, the unit was installed in the steam duct used for system testing. A total of 167 hours were accumulated in this test setup. Following this test an ATP was completed and is presented on Figure 27.

2. EMI Test Per SS-1313-R, Rev. 1

The transducer was sent to Genisco Technology Corporation for EMI testing. As mentioned previously, the EMI was found to exceed the RF conducted susceptibility requirements. The data sheet from that test is presented on Figure 28. As a result of this test a filter system was developed that corrected the problem. The complete EMI test on transducer S/N 22321 is presented in Appendix A.

3. Steam Endurance Test

Following the EMI test the transducer was installed in the steam generator test fixture as previously described. The unit was functionally subjected to the steam environment for 216 hours or approximately 9 days. At this time the unit was removed from the steam fixture and subjected to an ATP checkout. The transducer exceeded the minimum allowable tolerance at all but the highest test pressure. The data sheets are presented on Figure 29. The unit was returned to the supplier and the sensing cavity was opened. No evidence of either corrosion or contamination was found. The transducer was given a detailed failure analysis.

4. Modification

As shown on Figure 25 the calibration shift was caused by the magnetic path problem as previously discussed. The calibration shift of both this transducer and transducer S/N 22321 are attributed to the same cause. This transducer is presently being updated to the 836706-2 configuration that eliminates magnetic flux leakage as discussed in Figure 25.

Transducer 836706-2, S/N 22323 Testing

This transducer configuration is revised to include the fixes determined to be necessary during the previous tests. The unit, however, did not incorporate a silicone adhesive for improved cover and electrical connector to case sealing. A gasket was used for this unit. The gasket is not considered to be a sufficient moisture barrier and the use of the silicone adhesive will ensure a positive seal.

AIRESEARCH MANUFACTURING DIVISION
Los Angeles, California

DTD-191
Page 7

11

1. Extreme Temperature Test

Before the start of this test, to check the repeatability of the transducer, two calibrations were made 24 hours apart. As shown on Figure 30 the two calibrations were very close. Three of the calibration points on the second calibration check were made following a proof pressure of 22.5 psia. This test illustrates the high pressure margin and the excellent stability of this transducer.

The transducer was then subjected to temperature extremes at 0, 150, and 200°F with intermediate room temperature calibration checks. These results are also shown on Figure 30. The calibration was well within the nominal range for all these tests.

2. Pressure Cycling Test

Following the temperature cycling test, the transducer was subjected to 20,000 working pressure cycles and 500 ambient range pressure cycles. Working pressure cycles were between 0.05 and 0.30 psia and ambient range cycles were between 0 and 14.7 psia. The results of the calibration check following this test were well within the acceptable limits (in a band of $\pm 1.5\%$) and are shown on Figure 30.

3. Steam Endurance Test

The transducer was installed in the continuous steam generator and functionally subjected to 360 hours or over 15 days exposure. Following this exposure the unit was subjected to a post-test ATP calibration check. The data sheets, Figure 31 show the unit was within the nominal tolerances.

4. Water Test

The water soak test is presently in progress on this transducer. At this time the transducer has completed three out of four of the projected water soak cycles.

For this test, the transducer sense chamber is vacuum filled with distilled water and allowed to stand for approximately 48 hours. The water is then removed by heating to 150°F in a vacuum. The transducer is then checked for calibration shift.

Four water soak cycles as described above, are planned for this test. Three cycles are complete and the results are presented in the following figures:

<u>Figure</u>	<u>Calibration</u>
32	After first soak
33	After second soak
34	After third soak

The transducer is presently in its fourth and last cycle. As shown by the data sheets, the calibration has remained within acceptable limits.

CONCLUSIONS AND RECOMMENDATIONS

Based on the encouraging results of the testing completed to date, AiResearch has decided to submit an EDCP for the incorporation of the P/N 836706-2 Pace-Wiancko transducer in the Item 8.17 steam duct pressure application. At this time the transducer has proved its ability to retain a calibration within the required tolerance range.

The problems experienced with unit Serial Numbers 22321 and 22322 have apparently been successfully resolved by the changes incorporated for the 836706-2 configuration. The transducer, revised to that configuration, has been shown to remain stable and well within the required tolerance range.

The water soak tests, conducted on the new configuration, have not shown any indication of the extreme calibration drift that was experienced on the S/N 22319 transducer. This further supports the conclusion that the impurities contained in the tap water were a contributing cause of that calibration change.

The upward shift of the transducer output experienced on S/N 22321 and 22322 was attributed to an undesirable feature of the transducer magnetic circuit. The revised configuration, S/N 22323 incorporates an inconel ring around the "E" core which provides a high reluctance path between the "E" core and the magnetically permeable stainless steel case half. In the previous design, magnetic leakage through the case half formed a part of the path through the diaphragm and back to the "E" core. This leakage path plus minute shifts within the "E" core assembly were the cause of the calibration shifts. The inconel ring used in the new design provides a high reluctance path that attenuates case half leakage and reduces the transducer sensitivity to these minute shifts within the "E" core assembly. The sensor output is increased by an appreciable factor because of the resulting magnetic field concentration. The output was further increased by increasing the diaphragm movement from 0.0005 to 0.001 inch.

This approach has been used as a fix for a similar instability problem experienced on a ΔP transducer for the Grumman LEM application. According to Pace-Wiancko that unit has been successfully qualified.

The transducer initially had an EMI problem having exceeded required limits in the radio frequency conducted susceptibility test. This problem was resolved by inclusion of an improved EMI filter system.

To further prove the integrity of the 836706-2 configuration, the development tests are continuing and will include further functional steam testing, corrosive contaminant oxygen-humidity testing, and disassembly inspection of the units following the test program.

Part Number 837036-2, S/N 22322 (Continued)

	Steam Endurance Test	Ran a total of 216 hours on a steam generator. Unit was out of calibration on a subsequent ATP test.	29
	Modification	Returned transducer to supplier--opened chamber no contamination or corrosion noticed. Failure analysis conducted and unit is now being modified to 836706-2 configuration.	25

Part Number 836706-2*, S/N 22323

16 Nov 1967 to present	Initial Calibration	Passed	30
	Extreme Temperature Test	Passed	30
	Pressure Cycling Test	20,000 working cycles and 500 ambient range cycles	30
	Steam Endurance Test	Ran a total of 360 hours on a steam generator. Unit was within tolerance on a subsequent ATP	31
	Water Test	Filled sensing cavity with 32, 33, distilled water. Presently and 34 in fourth water soak	

* This transducer did not incorporate the silicone adhesive case sealing of this configuration, otherwise it is identical.

FAILURE ANALYSIS

PART NO. 601555 SERIAL NO. 22321 CUSTOMER P/N 837036-2-1 "L"

CUSTOMER S/N N/A CUSTOMER Airesearch

ANALYSIS: The upward shift of the transducers output has been explained as an undesirable feature of the magnetic circuit that was used. Magnetic leakage through the case half formed a part of the path through the diaphragm back to the "E" core. Minor shifts in the "E" core position due to instability in the potting compound would cause a reading offset.

CORRECTIVE ACTION: S/N 22323 incorporates an inconel ring around the "E" core which provided a high reluctance path between the "E" core and the magnetically permeable stainless case half. In the new design the inconel ring provides a high reluctance path that removes case half leakage from the magnetic circuit and reduces the reading sensitivity to movement of the "E" core. As a result of the concentration of the magnetic field the output of the pickup is increased by a noticeable factor. In addition to this the movement of the diaphragm in S/N 22323 has been increased from approx. .0005 to .001 inch. This has increased output.
